

A citation analysis examining geographical specificity in article titles

C. Sean Burns, Md. Anwarul Islam

Abstract

This investigation explores the impact of geographical names within article titles on citation frequency across a corpus of literature within the field of library and information science, spanning from 2018 to 2020, and encompassing sixty-one journal titles. We hypothesized that the presence of geographical names of nations in article titles would negatively correlate with citation frequency. Our primary analysis of 1484 articles with geographical names versus 11652 without, revealed a statistically significant, albeit small, difference in median citations, favoring articles without geographical names ($mdn = 7$) over those with geographical names ($mdn = 6$). Contrary to our secondary hypothesis, a proximity analysis demonstrated a weak, positive correlation between the closeness of geographical names to the title end and citation counts. Additionally, our examination found no evidence supporting differential citation frequency based on the Human Development Index (HDI) of the nations mentioned in titles, nor did the impact factor of the journal moderate the relationship between geographical names and citation frequency. A weak, negative correlation was discovered between the frequency of geographical names in journal titles and the journals' impact scores, yet this was not statistically significant. Our data also suggested a vague positional preference for nations within titles, unrelated to HDI. Furthermore, the likelihood of journals publishing articles mentioning nations of varying HDI was found to be statistically insignificant. This study sheds light on the nuanced influence of title specificity, through geographical names, on scholarly communication and citation impact, indicating a slight preference for broader title phrasing in garnering citations.

Keywords: Human Development Index, scholarly communication, scholarly writing, nation names, library and information science

Introduction

A well-crafted article title informs and can serve to attract readers. Authors must write titles that succinctly capture the central theme of their paper. Since titles function within the knowledge creation process, titles reflect disciplinary identity and expectations (Milojević 2017). In some disciplines, like math, titles focus on succinctness. Yet in other areas, like the social sciences, titles stress informativeness. In the medical sciences, the use of questions in titles has increased substantially since the 1960s, showing also geographical trends, representing perhaps institutional pressures to publish faster (Ball 2009).

The necessity to promote academic papers, to express disciplinary identity, to provide information, and other factors leads to various naming conventions, such as the use of colons in titles. Titles with colons (compound titles) are less succinct and potentially more informative. They move from making general statements (left of colon) to specific statements (right of colon). The specificity ranges from descriptive to declarative statements. Succinct titles may focus on providing topical information. Compound titles may add information about the method, research design, results, or conclusion of a study (Li and Xu 2019).

Title informativeness can be helpful when searching literature for a topic. The informativeness of a title can be a function of the words it contains and its length or word count. In the economics literature, longer titles receive more citations (“the informative effect”) than succinct titles (“the succinct effect”), but this is only true after the year 2000. Guo et al. (2018) attributes this to the rise of online searching, where retrieval technology is based on relevance algorithms that index keywords in various bibliographic fields. Li and Xu (2019) found that title length started to increase during this time frame, but defined title informativeness not

solely based on word count but on the proportion of content words (e.g., nouns, verbs, adverbs) to function words (e.g., pronouns, prepositions, conjunctions). Titles with a higher ratio of content words are more informative. This may be complicated though if function words are overly specific, obscure, or non-normative in some way (Fox and Burns 2015; Thelwall 2017).

If a title poorly captures the information about the content of a paper, then papers may be overlooked by searchers even if the papers are relevant to them. Alternatively, if title information is framed in such a way as to seem non-applicable, even if the paper is relevant to a searcher, then such papers may be overlooked. For example, papers with titles that ask questions have been shown to receive more downloads but fewer citations than papers with other title types (Jamali and Nikzad 2011; Paiva et al. 2012). This suggests that the information captured by a question-type title is trendy, not informative, or that the authors are less certain of the findings. However, a disciplinary effect exists. Papers with titles that ask questions are cited more in the computer science literature (Fiala et al. 2021) but no citation effects were found for question-type titles in an ecology journal (Fox and Burns 2015).

As mentioned, the use of compound titles (titles with colons, hyphens, dashes) has grown in recent decades, especially in some research areas or disciplines. Li and Xu (2019) outline three types of compound titles that capture specific semantic content. These are titles that describe the topic and the method or design, titles that describe the topic and the results, and titles that describe the topic and the conclusion of a study. Additionally, some authors add geographical names to compound titles, which may not add key semantic information about a paper’s topic (Kou et al. 2018). Studies have shown that papers with titles that contain certain types of highly specific or obscure content, like genus or species information (Fox and Burns 2015), or specific geographical place names, receive fewer citations (Abramo et al. 2016; Costello et al. 2019; Jacques and Sebire 2010; Moradi and Asnafi 2016; Paiva et al. 2012; Thelwall 2017). The common explanation is that this kind of taxonomic or geographic specificity is extraneous to the study, and that it reduces the generality and thus the appeal of the results reported in these papers to searchers or potential audiences (Fox and Burns 2015; Thelwall 2017). However, pointing to more disciplinary differences, specificity might be appreciated in some disciplines, like entomology, where titles with specific genus and species names or geographic names have been shown to have greater impact (Murphy et al. 2019).

Abramo et al. (2016) and others (Fox and Burns 2015; Thelwall 2017) have reasoned that overly specific terms or words in titles, especially those naming geographic entities, tend to receive fewer citations because searchers reviewing these titles do not find them relevant even if the topic is relevant. Abramo et al. (2016) suggested, for papers with geographical names in titles, that “studies conducted at the country level would typically be less appealing than [sic] those dealing with the same subjects at the broader level. The researcher [or potential reader] could suspect that certain results would be influenced by country-specific traits, and therefore be difficult to generalize” (p. 13). However, papers without specific geographical names in the titles might still be limited to specific geographical areas, and this raises questions not only about why some authors include geographical information in titles but also why some authors do not.

There is compelling evidence that the use of geographic names in article titles reveals potential biases in the representation of Western and non-Western populations in the CHI Conference Proceedings. Specifically, Kou et al. (2018) found that “studies conducted with non-Western populations are significantly more likely to highlight study contexts in titles and throughout the text,” and that “studies of Western countries are significantly more likely to lack mention of the studied countries not only in titles, but also throughout the text of the papers” (Kou et al. 2018, p. 2). Their findings also revealed that when country names were added to titles, they were often added at the end of a title, which suggested weak “semantic connections between the preceding ideas in the titles and the countries” (p. 8). Overall, their study suggests a geographical bias in the CHI literature to normalize findings based on Western populations and to exoticize findings based on non-Western populations. These findings, however, could be the result of researchers at or from Western nations conducting research on non-western populations, and may say little about how researchers use place names in titles when studying populations within their own nations.

Like Kou et al. (2018), our interest lies in examining the context in how authors use geographic names in titles. However, Kou et al. (2018) apply a simple binary classification of countries into Western and non-Western countries based on work by Huntington (2011). Burns and Fox (2017) use the Human Development Index

(HDI) (Nations 2023), a compound index that measures a nation’s level of health, education, and standard of living, in order to identify more nuanced patterns in how countries are named in paper titles. Based on this, we ask the following questions for the current study:

RQ: Does the inclusion of geographical names in the titles of journal articles impact their citation counts, after accounting for the Human Development Index score for the named location?

In order to answer these questions, we propose the following hypotheses:

- Main Hypothesis: Journal articles with geographical names in their titles are cited less frequently than those without geographical names.
 - Sub-Hypothesis 1: The closer a geographical name is to the end of the title, the fewer the citations the article would receive.
 - Sub-Hypothesis 2: Articles that mention nations with a higher Human Development Index in their titles are cited more frequently than articles that mention names with a lower Human Development Index.
 - Sub-Hypothesis 3: The impact of geographical names in titles on citation counts is moderated by the impact of the journal.
 - Sub-Hypothesis 4: Journals with a high frequency of articles with geographical names in titles have a lower impact compared to journals with a low frequency of articles with geographic names in article titles.
 - Sub-Hypothesis 5: Nations with lower HDIs will more likely appear toward the end of article titles than nations with higher HDIs.
 - Sub-Hypothesis 6: Journals may be more or less likely to publish articles that mention nations with higher or lower HDIs.

Materials and Methods

Our data is focused on articles published in library and information science (LIS) journals, as broadly categorized and listed by Scimago’s Scientific Journal Ranking (SJR) and the Scimago Journal and Country Rank (2021) data. We limited our set of articles to the 61 journals ranked in the first quartile (Q1) of the LIS category. We conducted Scopus queries for each journal in this list and downloaded bibliographic records for articles published in these journals from 2018 to 2020 (Fig. 1). We limited our data to the three year time period in order to align with the Scimago journal ranking time frame. We retrieved 13145 article records across the 61 journals. For example, our Scopus query for the journal *International Journal of Information Management* was:

```
SRCTITLE ( "International Journal of Information Management" ) AND (
LIMIT-TO ( PUBYEAR , 2020 ) OR LIMIT-TO ( PUBYEAR , 2019 ) OR LIMIT-TO
( PUBYEAR , 2018 ) ) AND ( LIMIT-TO ( DOCTYPE , "ar" ) )
```

Fig. 1: Example Scopus query to retrieve bibliographic records from one journal.

We combined and imported the bibliographic records into R using the bibliometrix package (Aria and Cuccurullo 2017). We used the Python *spaCy* natural language processing library to identify country names from article titles (Honnibal and Montani 2022). We manually reviewed and revised the data after locating false positives or negatives. This resulted in 1493 (11.36%) article titles with place names. We added the 2021-2022 Human Development Index (HDI) from the United Nations (UN) Development Programme that matched the country in the titles. The HDI summarizes three indices: a life expectancy index, an education index, and GINI index for measuring income inequality.

The Python *spaCy* library identified country names from constituent locales, such as specific states in the U.S. Thus, if an article title mentioned a place like “Alaska”, then we used “United States” for the nation and HDI variables. Alternatively, if a title included a term like “american”, the *spaCy* library was able to reference this as the *United States*. Therefore, when titles included place name variations, we referred to the canonical name for the nation referenced or inferred in the title.

We were interested in the location of the place name in each article title. We wrote a Python script, calling the *spaCy* natural processing library, to detect the position of the nation names in article titles. We manually reviewed all titles to address false positives and negatives. The position of places in article titles was scored on a scale of 0 to 1.0, with nations appearing as the last word in a title receiving a score approaching 1.0. Titles that did not contain a reference to a geographical region scored a zero. In cases where multiple countries were named in the title, the score was based on the first instance.

Most places named in titles matched names in the HDI. However, some articles had titles with nation names that for political reasons do not have an HDI (e.g., Taiwan and North Korea). These were marked as NA in the HDI variable. This reduced titles with nation names and HDI scores to 1484 records (Table 1). If a place was part of a broader collective (e.g., Scotland or Puerto Rico), we chose the HDI for the broader political authority (i.e., the United Kingdom or the United States, respectively). The HDI includes region level values: when article titles referenced Africa, we used the HDI for “Sub-Saharan Africa”, or when article titles referenced Europe, we used the HDI for “Europe and Central Asia” ($n = 154$). When multiple place names appeared in the title ($n = 94$), we averaged the HDI scores. The UN classifies HDI scores into four categories: very high (≥ 0.8), high (≥ 0.7), medium (≥ 0.55), and low (≤ 0.549). The averaged HDI for titles that mention multiple locations was very high on the HDI scale ($m = 0.858$; $mdn = 0.867$), indicating that nations with very high HDIs collaborate with nations that also have very high HDIs. However, the overall average HDI scores indicate that most nations or places named in article titles are nations or places with very high HDI scores ($m = 0.814$; $mdn = 0.838$).

Table 1: Table 1. Top 20 Most Frequent Nations

nation	n
china	183
spain	157
us	140
eu	86
uk	65
india	51
nigeria	40
africa	38
australia	37
brazil	33
south africa	26
canada	23
italy	23
russia	23
korea	20
pakistan	17
germany	16
latin america	16
mexico	15
cuba	14

Finally, we added SCImago Journal Rank (SJR) scores for each of the 61 journal titles in the data set. We use the SJR to control for citation effects across articles. SJR scores ranged from 0.528 to 4.584 for the publication titles in the data. A SJR score below 1.0 indicates below average citations compared to all journals in *Scopus*. The average SJR in the data was above average ($m = 1.333$; $mdn = 1.055$). However, after deduplicating publication titles and counting only unique journal titles, the average SJR in the data was lower ($m = 1.155$; $mdn = 0.848$), indicating publication titles with higher SJR scores appear more frequently in the data.

Results

This research aimed to investigate the relationship between the presence of geographical names in journal articles and their citation counts. We tested several hypotheses to understand the nuances of this relationship. Overall, we found that there was a small citation effect on journal articles that contained place names in titles. Articles that contained place names received significantly but slightly fewer citations, on average, than articles without place names. However, we were unable to associate this effect in any of our additional hypotheses. We present the results below.

Hypotheses

Main hypothesis: We hypothesized that journal articles with geographical names in their titles ($n = 1484$) are cited less frequently than those without geographical names ($n = 11652$). The Mann-Whitney U test revealed a statistically significant difference in citation distributions between articles with and without geographical names in their titles ($p < 0$). Further analysis showed a small citation effect. Articles with geographical names had a slightly lower average citation count ($mdn = 6$) than those without geographical names ($mdn = 7$).

Sub-Hypothesis 1: We hypothesized that the nearer a place name is to the end of the title, the fewer the citations the article would receive. In the data, we found some evidence in the data for the opposite relationship. Specifically, we found a statistically significant, positive correlation, ($\rho = 0.094$; $p < 0$), indicating that the closer a place name was to the end of a title, the more citations it received. However, the correlation although significant was weak (Fig. 2).

pdf

Sub-Hypothesis 2: We found no evidence to support our hypothesis that articles mentioning nations with a higher Human Development Index in their titles were cited more frequently than articles mentioning name with a lower Human Development Index. The correlation between the HDI of a nation named or inferred in a title was neither significant nor strong ($\rho = 0.004$; $p = 0.868$).

Sub-Hypothesis 3: We hypothesized that the impact of geographical names in titles on citation counts would be moderated by the impact of the journal. We found that the impact of the journal does not appear to play a moderating role in the relationship between geographical names in article titles and citation counts, based on the data. Specifically, our data shows that any relationship is likely due to random chance ($p = 0.392$).

Sub-Hypothesis 4: We hypothesized that journals that publish a high frequency of articles with geographical names in titles are journals that have lower impact scores. We found some evidence that journals that publish more articles with place names are less likely to have higher SJR scores. However, our data indicated a weak, negative correlation between the frequency with which a journal publishes articles with place names in titles and the journal's impact score ($\rho = -0.19$; $p = 0.143$) (Fig. 3).

pdf
2

Sub-Hypothesis 5: We hypothesized that there would be a relationship between the position of a place name in the title and the HDI of the nation named: specifically, that nations with lower HDIs will more likely appear toward the end of article titles. We found that nations appear more often in different positions in the article titles, but we could not find an explanation of this relationship from our data (Fig. 4). Specifically, we found a weak, negative correlation between the average position of a named place in a title and the HDI of the named place ($\rho = -0.146$; $p = 0.476$). Although our data suggests that different nations appear in different average positions in titles, this does not appear to be due to the nation's HDI score.

pdf
2

Sub-Hypothesis 6: We hypothesized that journals may be more or less likely to publish articles that mention nations with higher or lower HDIs. We found no evidence to suggest a relationship between the frequency journal titles include articles that mention place names and the HDIs of the named nations ($\rho = 0.119$; $p = 0.387$) (Fig. 5).

Discussion

Based on the results of other studies that have found that titles that were overly specific about certain factors were cited less (Fox and Burns 2015; Thelwall 2017), we developed a hypothesis that journal articles with geographical names in their titles would be cited less frequently than those without geographical names (Abramo et al. 2016; Costello et al. 2019; Jacques and Sebire 2010; Moradi and Asnafi 2016; Paiva et al. 2012; Thelwall 2017). Like Kou et al. (2018), we found evidence to support this hypothesis that there is a preference for generality in article titles; however, although the difference was statistically significant, the effect size was minimal. Additionally, all sub-hypotheses mostly yielded non-significant results or showed weak relationships. These results indicated that the reasons behind this phenomenon are complex, poorly explained by variables examined in this study, or simply that the evidence that supports our main hypothesis is too weak because there is no relationship.

Further research might explore other potential factors that influence citations to articles with place names. These factors may include the specific content of the articles, the information presented in the abstracts, the disciplines of the journals, broader cultural or academic trends, or the language or the coauthorship characteristics of the articles. Also, the small citation difference observed in the main hypothesis may be the result that papers with place names in their titles are read and cited heavily by regional author networks (Chinchilla-Rodríguez et al. 2014). That is, if further studies examine the citation networks of articles that include place names, we hypothesize that there is a substantial within-nation network citation advantage to including place names in articles, especially if geographical context plays an important role in a study (Murphy et al. 2019). For example, articles that include the geographical name “Bangladesh” or “United Kingdom” might tend to attract citations from others in Bangladesh or the United Kingdom, respectively. Such localized citations could be a reflection of the article’s relevance to that particular context. Thus, while including a geographical name might lead to a perceived loss of generality and thus less applicable to a broader audience, this disadvantage might be offset by the strength of importance of a study within a region. In a sense, research is local.

Although papers that reference country names in titles received fewer citations, we could find no relationship between the development level of a named country with the number of citations. We could also find no strong relationship between the location of the country name in the title with the article’s citations. Overall, there does not seem to be a geographical bias against specific countries in our data.

Limitations

It could be that citation differences between article titles with place names and without place names are more pronounced when sampling from lower impact journals or when sampling journals in other disciplines. Here, we only considered LIS journals. A future study with journals from other disciplines can add evidence to support the present result that we got from this study. The results could be different with a longer citation window. We also did not control for other factors, such if a title contains a colon, a question, or humor.

Conflicts of Interest: The authors have no relevant financial or non-financial interests to disclose. No funding was received for this work.
